TOPE ALABI SOCIAL MEDIA PERFORMANCE ANALYSIS

Important: The supplied dataset is simulated/AI-generated and should not be treated as actual account analytics.

1. Total views by platform (SUMIF)

Platform	Total Views
Instagram	131000
Facebook	179600
YouTube	239800

8. Chart observations

• YouTube has the highest total views (239,800), followed by Facebook (179,600).

• Instagram has the lowest total views (131,000) in this sample.

2. Highest likes (MAX)

Highest likes	9,200

Full ministration on YouTube has 9,200 likes, the highest in the sample. This suggests performance/ministration content may appeal strongly to viewers.

3. View categories (IF)

High Views posts	9

9 posts have at least 30,000 views.

3. View categories (IF)

Low Views posts	6

6 posts have fewer than 30,000 views.

4. Highest total interactions

Highest interactions	12,280

Full ministration on YouTube has the highest total interactions: 12,280.

5. Highest engagement rate

Highest engagement rate	17.61%

Audience testimony on Facebook has the highest engagement rate, about 17.61%. Engagement rate measures interactions relative to views, so a post can be more engaging proportionally without having the most views.

6. Average views by post type

Post Type	Average Views
Video	43,790.00
Reel	27,766.67
Image	14,600.00

Videos perform best by average views (43,790), followed by Reels (27,766.67) and images (14,600).

7. Number of posts by platform

Platform	Number of Posts
Instagram	6
Facebook	5
YouTube	4

The sample is uneven: Instagram has 6 posts, Facebook 5, and YouTube 4. Unequal counts can make comparisons less fair, so compare totals alongside per-post averages and engagement rates.

9. Recommendations

Give YouTube video content more attention because YouTube has the most total views (239,800) and videos have the highest average views (43,790). Also test Facebook audience-testimony posts because the Audience testimony post had the highest engagement rate (17.61%). Track results with real platform analytics before making major changes.

10. AI, data quality, and responsible

1. The data is simulated/AI-generated, so it may not match Tope Alabi's real account performance.

2. Platforms define and count views and interactions differently, so the numbers are not perfectly comparable.

3. Views may include repeat views and do not necessarily represent unique people; the sample is also small and has unequal post counts.

AI can quickly calculate totals, identify patterns, compare post types, and suggest questions to investigate. Its conclusions must be checked against original analytics, definitions, dates, and possible errors before decisions are made about actual performance.
